Why studying quantum computation?

Quantum is trendy ...

Research on quantum technologies is **speeding up**, and has already **created first operational and commercially available applications**.

For the first time the viability of quantum computing may be **demonstrated in a number of problems** and **its utility discussed across industries**.

Efforts, at national or international levels, to further **scale up** this research and development are in place.

Why studying quantum computation?

... and full of promises ...

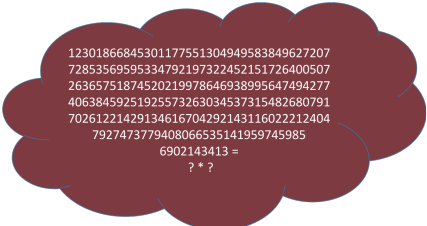

- Classical computer technology is running up against **fundamental size limitations** (Moore's law),

- Real difficult, complex problems remain **out of reach** of classical supercomputers

Why studying quantum computation?

Prime factorization

- Classically believed to be **superpolynomial in $\log n$** , i.e. as n increases the worst case time grows faster than any power of $\log n$.
- From the best current estimation (factoring a 130 digit number takes around one month in a massively parallel computer network) one can extrapolate that to factor a 400 digit number will take about the age of the universe (10^{10} years)

Why studying quantum computation?

However, a quantum algorithm exists such that

Factoring is achieved in **polynomial** time

Actually,

- Quantum computing will have a **substantial impact on societies**,
- even if, being a so **radically different technology**, it is difficult to **anticipate its evolution**.

Quantum Mechanics ‘meets’ Computer Science

Two main intellectual achievements of the 20th century met

- Computer Science and Information theory progressed by **abstracting** from the physical reality. This was the key of its success to an extent that **its origin was almost forgotten**.
- On the other hand **quantum mechanics** ubiquitously underlies ICT devices at the implementation level, but had no influence on the **computational model** itself ...
- ... until **now!**

Quantum Mechanics 'meets' Computer Science

Alan Turing (1912 - 1934)

Simulating Physics with Computers (1982)
(quantum reality as a computational resource)

Quantum effects as computational resources

Superposition

Our perception is that an object — e.g. a **bit** — exists in a well-defined state, even when we are not looking at it.

However: A quantum state **holds information of both possible classical states**.

Entanglement

Our perception is that objects are directly affected only by nearby objects, i.e. the laws of physics work in a local way.

However: two qubits can be connected, or **entangled**, st an action performed on one of them **can have an immediate effect on the other** even at distance.

Quantum effects as computational resources

God plays dice indeed

Our perception is that the laws of Physics are deterministic: there is a unique outcome to every experiment.

However: one can only know the **probability** of the outcome, for example the probability of a system in a superposition to collapse into a specific state when measured.

Uncertainty is a feature, not a bug

Our perception is that with better tools we will be able to measure whatever seems relevant for a problem.

However: there are **inherent limitations** to the amount of knowledge that one can ascertain about a physical system

Quantum Computation

computability

Bits as vectors

Classical bits, standing for Boolean values 0 and 1, can be represented by vectors:

$$|0\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad |1\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

If rows are labelled from 0 onwards, the presence of 1 in a cell identifies the number represented by the vector.

Larger state spaces are built with the (Kronecker) **tensor** product:

$$\begin{bmatrix} p_0 \\ p_1 \end{bmatrix} \otimes \begin{bmatrix} q_0 \\ q_1 \end{bmatrix} = \begin{bmatrix} p_0 \begin{bmatrix} q_0 \\ q_1 \end{bmatrix} \\ p_1 \begin{bmatrix} q_0 \\ q_1 \end{bmatrix} \end{bmatrix} = \begin{bmatrix} p_0 q_0 \\ p_0 q_1 \\ p_1 q_0 \\ p_1 q_1 \end{bmatrix}$$

Bits as vectors

Examples: Putting bits together

$$|00\rangle = |0\rangle \otimes |0\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \otimes \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

$$|4\rangle = |100\rangle = |1\rangle \otimes |0\rangle \otimes |0\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \otimes \begin{bmatrix} 1 \\ 0 \end{bmatrix} \otimes \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

Bits as vectors, operators as matrices

$$\boxed{I(x) = x}$$

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

$$\boxed{X(x) = \neg x}$$

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

$$\boxed{\underline{1}(x) = 1}$$

$$\begin{bmatrix} 0 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad \begin{bmatrix} 0 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

$$\boxed{\underline{0}(x) = 0}$$

$$\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

$$\begin{aligned} I|0\rangle &= |0\rangle & I|1\rangle &= |1\rangle \\ X|0\rangle &= |1\rangle & X|1\rangle &= |0\rangle \\ \underline{1}|0\rangle &= |1\rangle & \underline{1}|1\rangle &= |1\rangle \\ \underline{0}|0\rangle &= |0\rangle & \underline{0}|1\rangle &= |0\rangle \end{aligned}$$

Composition

Sequential composition: **matrix multiplication**

Parallel composition: **Kronecker product** \otimes

$$M \otimes N = \begin{bmatrix} M_{1,1}N & \cdots & M_{1,n}N \\ \vdots & & \vdots \\ M_{m,1}N & \cdots & M_{m,n}N \end{bmatrix}$$

for example

$$X \otimes \underline{1} \otimes I |101\rangle = X \otimes \underline{1} \otimes I (|1\rangle \otimes |0\rangle \otimes |1\rangle) = X|1\rangle \otimes \underline{1}|0\rangle \otimes I|1\rangle = |011\rangle$$

Probabilistic bits

State: is a **vector of probabilities** in \mathcal{R}^n

$$[p_0 \cdots p_n]^T \text{ such that } \sum_i p_i = 1$$

which express **indeterminacy** about the system's exact physical configuration

Operator: is a **double stochastic** matrix where $M_{i,j}$ specifies the probability of evolution from state j to i

Qubits are a different story

A quantum state holds the information of **both** possible classical states:

A **qubit** lives in a 2-dimensional complex vector space:

$$|\nu\rangle = \alpha|0\rangle + \beta|1\rangle$$

and thus possesses a **continuum of possible values**, so potentially, can store lots of classical data.

Qubits are a different story

However, all this potential is **hidden**:

when **observed** $|v\rangle$ **collapses into a classic state**: $|0\rangle$, with probability $|\alpha|^2$,
or $|1\rangle$, with probability $|\beta|^2$.

The outcome of an observation is **probabilistic**, which calls for a restriction to **unit** vectors, i.e. st

$$|\alpha|^2 + |\beta|^2 = 1$$

to represent quantum states.

Qubits are a different story

But a **superposition** state is **not** a probabilistic mixture: it is **not** true that the state is really either $|0\rangle$ or $|1\rangle$ and we just do not happen to know which.

Amplitudes are not real numbers (e.g. probabilities) that can only increase when added, but **complex** so that they can cancel each other or lower their probability.

Superposition in action: A random number generator

By preparing deterministically a single qubit and measuring in the standard basis, we can achieve a task that it is impossible classically: a **true** random numbers generator.

- Prepare quantum state

$$|+\rangle = \frac{1}{\sqrt{2}}|0\rangle + \frac{1}{\sqrt{2}}|1\rangle$$

- Measure $|+\rangle$ in the computational basis to obtain either 0 or 1 with equal probability ($|\frac{1}{\sqrt{2}}|^2 = 0.5$)

This algorithm allows us to produce a perfect random number even though no randomness has been used inside it

Quantum bits: An experiment with a photon

$|0\rangle$ - horizontal polarization

$|1\rangle$ - vertical polarization

$$|+\rangle = \frac{1}{\sqrt{2}}|1\rangle + \frac{1}{\sqrt{2}}|0\rangle$$

(from [Reifell & Polak, 2011])

Quantum bits: An experiment with a photon

For a beam of light there is a classical explanation in terms of waves. But that does not work for a **single** photon experiment.

An explanation

- The photon's polarization state is modelled by a unit vector, for example $|+\rangle = \frac{1}{\sqrt{2}}|1\rangle + \frac{1}{\sqrt{2}}|0\rangle$, which corresponds to a polarization of 45 degrees.
- ... or, in general, a vector

$$|v\rangle = \alpha|0\rangle + \beta|1\rangle$$

where α , β are (complex) **amplitudes**.

If α , β are both non-zero, $|v\rangle$ is said a **superposition** of $|0\rangle$ and $|1\rangle$

Quantum bits: An experiment with a photon

- Each polaroid has also a polarization axis.
- On passing a polaroid the photon becomes polarized in the direction of that axis.
- The probability that a photon passes through the polaroid is the square of the magnitude of the amplitude of its polarization in the direction of the polaroid's axis.

For example, if the photon is polarized as $|\nu\rangle$ it will go through A with probability $|\alpha|^2$ and be absorbed with $|\beta|^2$.

Quantum bits: An experiment with a photon

The polarization of polaroid B is

$$|+\rangle = \frac{1}{\sqrt{2}}|1\rangle + \frac{1}{\sqrt{2}}|0\rangle$$

i.e. represented as a **superposition** of vectors $|0\rangle$ and $|1\rangle$

Quantum bits: An experiment with a photon

Expressing $|0\rangle$ in terms of the Hadamard basis

$$|+\rangle = \frac{1}{\sqrt{2}}|0\rangle + \frac{1}{\sqrt{2}}|1\rangle$$

$$|-\rangle = \frac{1}{\sqrt{2}}|0\rangle - \frac{1}{\sqrt{2}}|1\rangle$$

yields

$$|0\rangle = \frac{1}{\sqrt{2}}|-\rangle + \frac{1}{\sqrt{2}}|+\rangle$$

which explains why a visible effect appears when the last polaroid is introduced:

the photon goes through C with 50% of probability (i.e. $|\frac{1}{\sqrt{2}}|^2 = \frac{1}{2}$).

Quantum bits: An experiment with a photon

Concluding

- Photon's polarization **states** are represented as unit vectors in a **2-dimensional complex vector space**,.
- The interaction of a photon with the polaroid is **probabilistic** and depends on the **amplitude** of the photon's polarization in the direction of the polaroid's axis.
- Either the photon will be absorbed or leave the polaroid with its polarization aligned with the polaroid's axis.

Qubits

Photon's polarization **states** are represented as unit vectors in a **2-dimensional complex vector space**, typically as a

non trivial linear combination \equiv **superposition** of vectors in a basis

$$|v\rangle = \alpha|0\rangle + \beta|1\rangle$$

A basis provides an **observation** (or **measurement**) tool, e.g.

$$\bigcirc \frown \bigcirc = \{|0\rangle, |1\rangle\} \quad \text{or} \quad \bigcirc \frown \bigcirc = \{|-\rangle, |+\rangle\}$$

The space of possible polarization states of a photon is an example of a **qubit**

Superposition and interference

Observation of a state

$$|v\rangle = \alpha|u\rangle + \beta|u'\rangle$$

transforms the state into one of the basis vectors in

$$\bigcirc \smile \bigcirc = \{|u\rangle, |u'\rangle\}$$

In other (the quantum mechanics) words:

measurement collapses $|v\rangle$ into a classic, non superimposed state

Superposition and interference

The **probability** that observed $|v\rangle$ collapses into $|u\rangle$ is the square of the modulus of the amplitude of its component in the direction of $|u\rangle$, i.e.

$$|\alpha|^2$$

where, for a complex γ , $|\gamma| = \sqrt{\gamma\bar{\gamma}}$

A subsequent measurement wrt the same basis returns $|u\rangle$ with probability 1

This observation calls for a restriction to **unit** vectors, i.e. st

$$|\alpha|^2 + |\beta|^2 = 1$$

to represent quantum states

Superposition and interference

The notion of **superposition** is **basis-dependent**: all states are superpositions with respect to some bases and not with respect to others.

But it is **not** a probabilistic mixture: it is **not** true that the state is really either $|u\rangle$ or $|u'\rangle$ and we just do not happen to know which.

State $|u\rangle$ is a definite state, which, when measured in certain bases, gives deterministic results, while in others it gives random results:

The photon with polarization

$$|-\rangle = \frac{1}{\sqrt{2}}|1\rangle - \frac{1}{\sqrt{2}}|0\rangle$$

behaves deterministically when measured with respect to the Hadamard basis but non deterministically with respect to the standard basis

Superposition and interference

In a sense $|u\rangle$ can be thought as **being simultaneously in both states**, but be careful: states that are combinations of basis vectors in similar proportions but with different amplitudes, e.g.

$$\frac{1}{\sqrt{2}}(|u\rangle + |u'\rangle) \quad \text{and} \quad \frac{1}{\sqrt{2}}(|u\rangle - |u'\rangle)$$

are distinct and behave differently in many situations.

Amplitudes are not real (e.g. probabilities) that can only increase when added, but **complex** so that they can **cancel each other or lower their probability**, thus capturing another fundamental **quantum resource**:

interference

Qubits

Any quantum system (e.g. photon polarization, electron spin, and the ground state together with an excited state of an atom) that can be modelled by a two-dimensional complex vector space, forms a

quantum bit (qubit)

which has a continuum of possible values.

- **In practice** it is not yet clear which two-state systems will be most suitable for physical realizations of qubits: it is likely that a variety of physical representation will be used.
- and they are **fragile** and **unstable** which entails the need for qubits' strong isolation, typically very hard to achieve.

Qubits

A qubit has ... a **continuum of possible values**

- potentially, it can store lots of classical data
- but the amount of information that can be extracted from a qubit by measurement is severely **restricted**: a single measurement yields at most a single classical bit of information;
- as measurement changes the state, **one cannot make two measurements on the original state** of a qubit.
- as an unknown quantum state **cannot be cloned**, it is not possible to measure a qubit's state in two ways, even indirectly by copying its state and measuring the copy.

Can we play the quantum game with a classical computer?

Simulating a computation with qubits in a classical computer would be extremely hard, i.e. extremely inefficient as the number of qubits increases:

- For 100 qubits the state space would require to store $2^{100} \approx 10^{30}$ complex numbers!
- And what about rotating a vector in a vector space of dimension 10^{30} ?

Thus,

Quantum computing as **using quantum reality as a computational resource**

Richard Feynman, *Simulating Physics with Computers* (1982)
